Abstract

Strategic trade refers to international trade under market imperfections. The purpose of the article is to comprehend general equilibrium implications of trade liberalization on Indian macroeconomic aspects under alternative market structures. We applied computable general equilibrium (CGE) modelling as our relevant methodology following Shoven and Whalley, (1984). Constructing a four sector social accounting matrix (SAM) for India, the article attempts to purport the effects of liberalized trade over different macroeconomic aspects under monopolistic competition and compared the results with the same obtained under benchmark perfect competition scenario. Our study reveals that trade under imperfect competition could not produce any greater domestic output, expansion of trade in terms of volume of export and import and gains from trade as compared to standard perfect competition scenario.

Keywords

CGE, SAM, monopolistic competition, trade liberalization

Introduction

This article attempts empirical implementation of a real trade general equilibrium model using computable general equilibrium (CGM) methodology for a small open economy that includes some features related to ‘industrial organization’ approach to trade. Theoretical study in this area has been developed rapidly by the works of Helpman (1981, 1982), Krugman (1979, 1980, 1981) and many others dealing with imperfect competition, economies of scale, entry barriers, product differentiation and few other aspects of industry structure while judging costs and benefits of trade liberalization. Very early works of Balassa (1966), Corden (1970, 1974), Eastman and Stykolt (1966) and Wonnacott and Wonnacott (1967) studied the role of scale economies and its impact on international trade and structure of the industry. Balassa (1966) and Grubel and Loyed (1975) reported that much trade takes place on intra-industry basis which provides solid foundation for inter-industry and intra-industry adjustment along with Heckscher–Ohlin argument of comparative cost advantage.

Argument from Industrial Organisation (IO) standpoint predicts that imposition of trade barriers restrict market size and foreign competition promoting too many home firms to operate in an industry exploiting too low scale of production (Krugman 1994, Ch. 14). Conventional analysis under perfect competition and constant return to scale predicts the cost of protection to be very small in the order of 0.5 to 2 per cent of the GDP. This empirical result is confirmed by Boardway and Treddnick (1978), Brown and Whalley (1980), Deardorff and Stern (1981), Dixon (1982), etc., based on the assumption of perfect competition. Contrary to those analyses, Balassa (1966) and Wonnacott (1975) reported much more higher gains from trade liberalization, obtained under the presence of scale economies and market imperfection than under conventional perfect competition based analysis.

Trade theory and industrial policies are such kind of economic policy which highly depends on general equilibrium structure of the economy. While conventional trade theory highly depends upon Heckscher/Ohlin framework, I/O approach is highly predominant towards partial

Pinaki Chakraborti, Professor, Department of Economics, Burdwan University, West Bengal, India. E-mail: c.pinaki@gmail.com

equilibrium framework. Theoretical works of Brander (1981), Helpman (1981), Krugman (1980) and Lancaster (1980) have been most important in this direction. Dealing with I/O approach to trade with empirical general equilibrium framework is likely to provide insightful implications. Important thing in the general equilibrium set-up of the open economy trade structure including I/O features is the assumption of inter-sectoral circular flows of commodities and basic factor services which is supposed to capture additional source of comparative cost advantage due to the presence of scale economy benefit along with other conventional sources like geographical factor endowment difference and technology difference.

Harris and Cox (1984) first constructed an empirical general equilibrium model of small open economy that incorporates many I/O features, seems to be important for an industry in a real economy such as semiconductor industry in the USA. and Japan (Baldwin & Krugman 1988). Their empirical general equilibrium model followed the methodology used by Shoven and Whalley (1984). Many such works in this direction established the fact that empirical results of a general equilibrium analysis incorporating I/O features differs significantly from the analysis that does not incorporate I/O features.¹ Perfectly competitive structure assumed in many CGE models usually understates gains from trade originated from the reduction of trade barriers. Empirical studies of Cox and Harris (1992) and Brown and Stern (1989) have shown that incorporation of imperfectly competitive sectors within CGE framework leads to substantial increase of welfare gains for Canada from the US–Canada free trade agreement.

In Indian context, noteworthy works on CGE modelling, like Panda and Quizon (2001), Panda and Kumar (2008) and Parikh et al. (1997), did not consider market imperfection explicitly in their empirical general equilibrium analysis. Several strategic aspects like, economies of scale and scope, competition among firms, product differentiation due to consumer's preference for varieties may give rise to different trade policy implications in a general equilibrium framework. In this article our intention is to introduce market imperfection explicitly in a benchmark perfect competition model and study the consequent trade policy implications.

Social Accounting Matrix

CGE models are traditionally based on social accounting matrix (SAM) which is matrix representation of all

transactions and transfers that takes place among different production activities, various factors of production and different institutions like households, corporate and government within the country and with respect to rest of the world in a particular financial year. SAM, therefore, defines a comprehensive framework that can depict full circular flow of income from production activities to factor service providers like households. Each row of a SAM represents total receipts of any account and column represents expenditure of that account. Therefore, row total is supposed to be equal with corresponding column total. An entry in the i th row and j th column represents receipts of i th account from the j th account. Schematic structure of SAM is depicted by Table 1.

A SAM is a database and extension over input/output matrix (I/O). Use of I/O matrix is widely accepted with the pioneering work of Wassily Leontief. I/O matrix however, does not represent interrelationship between factor value added and agent's final expenditure. Extension of an I/O table with the introduction agent's behaviour and institutional characteristics one can get essential features of a SAM. This can depict entire circular flow of income much more effectively. Our environmental CGE model is based on schematic structure of SAM and for calibration of the model we constructed Energy/Environmental SAM for India for the year 2003–2004 following Saluja and Yadav (2006).²

Structure of Benchmark CGE Model under Perfect Competition

Our benchmark CGE model is based on Perfect Competition and constant returns to scale assumption both in commodity market and factor market. Model is based on following assumptions.

Sectors and Agents

Following SAM for India of the year 2004 produced by Saluja and Yadav (2006) and Ojha (2009), Pohit et al. (2009) we grouped all sectors of the economy into four aggregated sectors, that is, (i) *Primary sector* consists of all agricultural products, minerals, primary products such as iron ores, crude petroleum and agro process activities; (ii) *Secondary sector* is comprised mainly of all manufacturing activities like, cotton and textile, plastic, rubber and lather products, cement, different chemical products etc.;

Table 1. Schematic Structure of SAM

	Activities (1)	Commodities (2)	Factors (3)	Households (4)	PVT Corp. (5)	Pub. Ent. (6)	Govt. (7)	Ind. taxes (8)	Capital A/C (9)	ROW (10)	Total
1	Activities	Gross output									Output
2	Commodities	Purchase of raw material		Household consumption			Government consumption		Gross Fixed Capital Formation	Exports	Aggregate demand
3	Factors	Value added								Net factor income	Factor Income
4	Household		Endowment of HH				Govt. transfer,			Net current transfer	Total Household income
5	PVT corp.		Operating Profits				Interest on debt				Income of Private Corporate
6	Pub. Ent.		Operating Surplus								Income of Public departmental
7	Government		Income from entrepr.	Income tax by households	Corporate taxes			Total indirect taxes		Net capital transfer	Total govt. earnings
8	Ind. tax	Taxes on intermediate		Taxes on purchases			Taxes on purchases		Taxes on investment	Tax on exports	Total Indirect taxes
9	Capital A/C		Depreciation	Household savings	Corporate savings	Public sector savings	Govt. savings			Foreign savings	Gross savings of economy
10	ROW	Imports									Foreign exchange payments
	Total	Total cost of production	Total factor endowments	Total use of HH income	PVT CORP income	Income of PSU	Aggregate govt. exp.	Total ind. tax	Aggregate investment	Foreign Ex. Recept.	

Source: Saluja and Yadav (2006).

(iii) *Infrastructural service* consists infrastructural service activities like Water supply, Travel and Transport, Railway, Hotel and Restaurant and Construction; (iv) *Other service sectors* like education, health care services, public administration, bank and insurance, postal services etc. We considered four types of agents in the economy, that is, Household, Firm, Government and Rest of the World (ROW). There are four types of households, that is, (i) RHH-1 (Rural agricultural and other labourers), (ii) RHH-2 (Agricultural self-employed and other households), (iii) UHH-1 (Urban salaried class) and (iv) UHH-2 (Urban casual labour and others). All other countries and regions are clubbed together into ROW.

Production and Factor Inputs

We have considered two basic factors of production, that is, labour and capital, that take part in the production process within which substitution is possible through Cobb–Dauglus production technology. Each production unit requires intermediate inputs following fixed coefficient type Lontief technology.

Prices

Product prices are determined from the equality of price and average cost. Average cost is comprised of basic factor cost, cost of intermediate inputs that includes cost of energy inputs. Increasing returns to scale is assumed through the presence of fixed cost in the production units.

Household Income and Expenditure

Households are rendering factor services in terms of labour and capital while in return they are receiving factor payments in the form of wages and rentals. We have considered four types of household, two of them are rural type and other two are urban type. Household spends his income for consumption purposes. We have assumed linier expenditure system type demand function for household.

Government Income and Expenditure

Sources of income for the government are (i) direct, indirect and corporate taxes, (ii) import tariff³ and (iii) income from entrepreneurial activity. In the expenditure front we

assumed government's expenditure in any sector is exogenously determined, that is, determined in the government's budget and adjusted to benchmark SAM. Difference between government's income and expenditure is government's savings.⁴

Investment and Savings

We considered Neo-classical type closure rule where investment is guided by saving. Total saving is comprised of (i) household saving, (ii) government saving, (iii) corporate saving and (iv) foreign savings. Total saving is converted to total investment.

Armington Function and Trade

International trade in our model is guided by Armington function. Total availability of composite commodity in the domestic economy is composed of domestically produced variety of the good demanded by the domestic people and foreign variety of the same good. Both types of variety are combined together following a Constant Elasticity of Substitution type preference function.

Production of Output and Transformation

Total supply of each domestic good produced using labour, capital and intermediate input is used up by export of that good and to meet up domestic demand of domestic variety. Both export and domestic demand of the produced good is combined together following CES type transformation function.

Factor Prices and Equilibrium

We consider two basic factors of production, that is, labour and capital. Total supply of basic factor is fixed in value terms and factor prices are flexible. Physical quantity of labour or capital may change in different simulation experiments following demand and supply equilibrium mechanism in the factor market. Demand for factor is originated from the production of goods and services.

Equilibrium in Commodity Market

In the commodity market total supply of the composite commodity is constituted by domestic variety as well as

imported foreign variety corresponds to each good. Demand for the composite commodity is generated from household consumption, government consumption expenditure, total investment demand and demand for intermediate input. Composite commodity price is determined from the demand and supply of composite commodity.

GDP and Welfare

Under perfect competition GDP has been computed adding all sectoral outputs. Social welfare has been of Cobb–Duaglus type and depends on private household consumption.

Inclusion of Market Imperfection in CGE Model

In our analysis we assumed presence of fixed cost in the production sector which gives rise to economics of scale at the firm level enabling the firms to have sufficient market power in respect of price setting. Firms may act cooperatively or non-cooperatively. In this point we have been restricted to non-cooperative behaviour of firms only as we followed Helpman and Knigman (1985)⁵ essentially.

The outcome of non-cooperative behaviour of firms in an industry depends on two factors: (i) Strategic aspects of non-cooperation and (ii) Condition of entry and exit in the industry. Most of the theoretical works on trade models incorporating oligopoly⁶ considered either output decision or price decision as strategic variables. In our analysis we followed Monopolistic Competition approach based on the assumption of Bertrand-type Competition where each firm takes rival’s price as given while taking decision over his own price. We also assume firms are able to differentiate their products such that products are not perfect substitute for those products of existing competitors as well as potential entrants. Here each firm is acting as monopolist facing downward sloping demand curve. Regarding entry we assumed no barriers to entry or free entry that drives profit to zero. This is known as Chamberlin’s ‘large group’ case which is quite consistent with Bertrand model.

Inclusion of Fixed Cost

We modelled fixed cost as the part of total cost which is invariant to output. In actual practice it is not the ‘sunk’ cost but a recurrent expenditure must be incurred by the

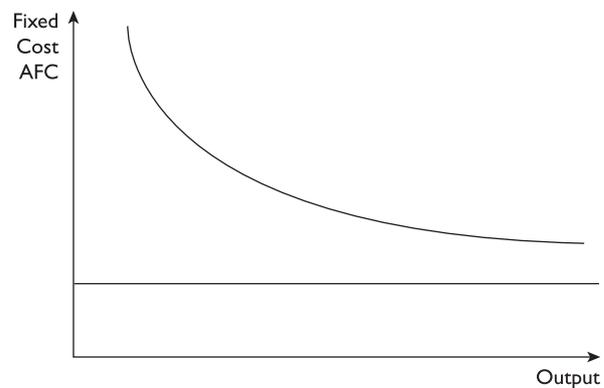

Figure 1. Falling Average Fixed Cost

firms in each year to carry on production process. For example, maintenance cost of building and construction, machinery, various equipments⁷ etc. We further assume certain part of the total capital cost is fixed cost which is independent of output. Presence of fixed cost implies, higher output production reduces per unit capital cost. This gives sufficient market power to the existing farms. According to our assumption scale economy is external to the firms but internal to the industry.⁸ Behavior of average fixed cost is represented by Figure 1.

$$pz(j) = \underbrace{ay(j) \times py(j)}_{\text{Basic Factor Cost}} + \underbrace{\sum_i ax(i, j) \times pq(i)}_{\text{Intermediate Input Cost}} + \underbrace{FC(j)/Z(j)}_{\text{Average Fixed Cost}}; \tag{1}^9$$

Above equation shows that average total cost is the sum of (a) Unit basic factor cost, (b) Unit intermediate input cost and (c) average fixed cost. Unit basic factor cost includes both labour and capital cost while capital cost excludes fixed cost.

Inclusion of Consumer’s Preference for Varieties

Theoretically there are two important factors that could comprehensively represent consumers’ preference for different varieties. They are (i) elasticity of substitution between varieties and (ii) number of varieties. Their inclusion into our CGE framework is as follows.

Elasticity of Substitution

We considered an indirect measure of Elasticity of Substitution parameter in terms of price elasticity of

demand faced by the firms. We borrowed our social welfare function from Krugman (1979) that takes price elasticities are different across industries as we find below:

$$\begin{aligned}
 W = & \log\left(\sum_{i=1}^{N_1} D_1^{\beta_1}\right)^{\frac{1}{\beta_1}} + \log\left(\sum_{i=1}^{N_2} D_2^{\beta_2}\right)^{\frac{1}{\beta_2}} \\
 & + \log\left(\sum_{i=1}^{N_3} D_3^{\beta_3}\right)^{\frac{1}{\beta_3}} + \log\left(\sum_{i=1}^{N_4} D_4^{\beta_4}\right)^{\frac{1}{\beta_4}} \quad (2) \\
 \beta_i \equiv & \left(1 - \frac{1}{\theta_i}\right)
 \end{aligned}$$

Here β_i is elasticity of substitution parameter for i th industry. N_i and D_i are the number of variety and domestic consumption of the i th product. W is social welfare.

Krugman (1979) also pointed out that social welfare function (2) has nice property that with large N each firm will face demand elasticity $= \frac{1}{1 - \beta_i} = \theta_i$.

When number of variety is large firms do not consider second term and so elasticity value becomes θ_i . When all varieties are equally priced second term becomes $\frac{(1 - \theta_i)}{N_i}$.

As number of variety is large second term vanishes. In our analysis price elasticity of demand for i th commodity is E_p .

Here $E_p = \theta_i + \left(\frac{1 - \theta_i}{N_i}\right)^{10}$. Now E_p value can be computed from our model and setting $N = 10^{11}$, we can compute θ_i which determines elasticity of substitution parameter in each sector. From our model we calculated price elasticity of demand for (i) Primary sector, (ii) Secondary sector, (iii) Infrastructure and (iv) Other service sector or as $-0.35215, -0.2642, -0.289, -0.3107$ respectively.¹²

Database and Calibration

The parameters of the constructed model are then estimated in conjunction with the benchmark dataset. In few instances, econometric estimates obtained from other sources have been applied for the purpose of parameter estimation. For example, number of varieties in the industry has been considered as 10 based on certain assumption. Remaining parameters are chosen, such that, they are consistent with the benchmark data. Here we have manipulated the equations of the model, so that parameters can be represented as the function of the data and solved the

equations to obtain parameter values. This process is known as calibration, a deterministic procedure, in which we get point estimates of the parameters without having any standard errors. Calibrated CGE model will be solved to check whether it can reproduce a replica of the benchmark data. If benchmark SAM is not regenerated during solve of the model, we have to respecify our model and reestimate the parameters until the model generates a replica of the benchmark SAM.

For the calibration of our model parameters we used SAM of India for the year 2003–2004 with four sectors, two basic factors and four types of households.¹³ Stepwise calibration process is presented in Figure 2. SAM of India 2003–04 is represented by Tables 2 and 3.

For the estimate of fixed cost, we assumed 10 per cent of the capital employed in the production process¹⁴ is invariant to output in each year. It indicates that, as output increases by 10 per cent, average capital cost will fall

by 1 per cent. For the social welfare function under imperfect competition, we have two determinants. First, the number of product variety in different sectors and second, elasticity of substitution between varieties corresponding to different sectors. For the first one we assumed, benchmark number of variety is 10.¹⁵ For the substitution elasticity, we consider the relationship with elasticity of demand and using sectoral price elasticities computed from our model we calculated elasticity of substitution between varieties.¹⁶ We have solved the model using GAMS package for benchmark equilibrium. SAM is regenerated during the process of calibration.

Simulation Experiments

After estimating the model parameters through benchmark equilibrium, we performed simulation experiments to obtain the impacts of policy change. We have changed the policy parameters appropriately and solved the model once again to obtain counterfactual equilibrium data values. We made three simulation experiments related to trade liberalization (i) 50 per cent reduction of import tariff, (ii) technological upgradation and (iii) greater foreign capital inflow. In order to obtain the impacts of policy changes, counterfactual equilibrium values are compared with benchmark equilibrium values of the macroeconomic variables.

EXPERIMENT 1 Import liberalization in the presence of increasing returns to scale and ‘Consumers preference for variety’.

We liberalized trade by 50 per cent tariff reduction in the presence of increasing returns to scale in production sector and consumers preference for variety in the demand side and compared the result with trade liberalization under perfect competition. We find import increases by 5.62 per cent as opposed to 6.81 per cent increase of import in case of perfect competition. Exchange rate depreciates by 1.748 per cent as opposed to 1.9 per cent in case of perfect competition. This led to reduced expansion of export by 4.94 per cent as opposed to 5.9 per cent in perfect competition. Reduced trade expansion is attributed due to the presence of ‘excess capacity’ in production that outweighs benefit from additional basis of comparative cost advantage, namely, ‘variety driven trade’ apart from factor endowment difference and technology difference. GDP in this process increases by 0.097 as opposed to 0.296 per cent in perfect competition case due to the presence of ‘excess capacity’ in production process that outweighs benefit from increasing return to scale. Sectoral

output increases in secondary sector, infrastructure and service sector where benefits of market imperfection like, increasing returns to scale and horizontal product differentiation owing to comer’s preference for product variety could have been reaped due to the presence of ‘excess unutilized capacity’ in those sectors. On the contrary, agricultural output could not be expanded due to capacity constraints like, inadequate supply of arable land, lack of technology adoption possibility etc. Composite commodity price has been reduced with lower percentage than under perfect competition. Sectoral changes of import remains similar while sectoral changes of export have been lower than that of under perfect competition. The number of product variety and consumer’s choice increases in all sectors excepting little reduction in infrastructural sector. Social welfare increases by 0.03 per cent as compared to 0.146 per cent in case of perfect competition. Even if consumers are gaining from increased product variety, there is some excess capacity loss in monopolistically competitive product market.¹⁷ This causes welfare to increase by lesser percentage than in perfect competition case. Mechanism of import liberalization is presented in Figure 3.

Under perfect competition long-run equilibrium takes place at the minimum point of the long run average cost (LAC) curve and satisfies the condition $P = AC = MR = MC$ while under monopolistic competition equilibrium

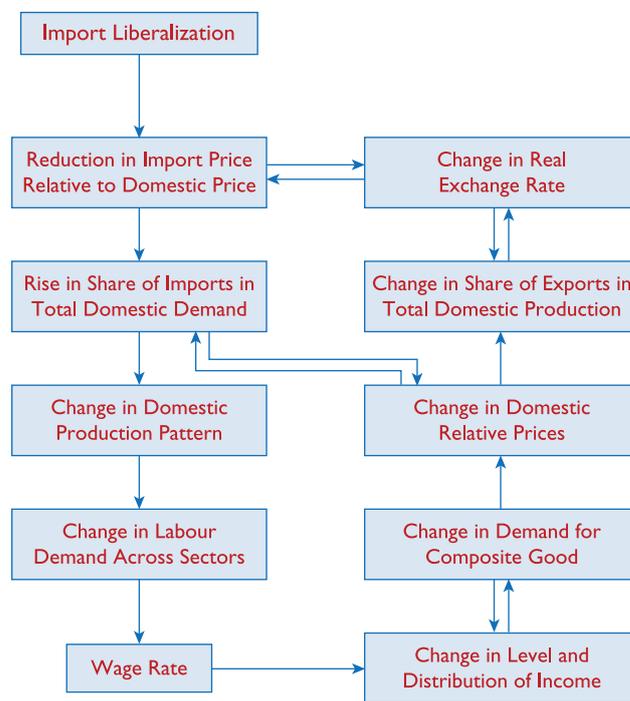

Figure 3. Major Interactions Due to Import Liberalization

takes place at the point of tangency of the demand curve to the LAC curve. At this point $MC = MR$ and $AC = P$, but $P > MC$. As the consequence, equilibrium price is higher and output is lower under monopolistic competition than under perfect competition.

Under monopolistic competition too many firms in the industry and each are producing an output less than optimal at a cost which is higher than minimum. In the Figure 4 ($Q_{IMP} - Q_{PER}$) depicts excess capacity present in the industry under imperfect competition.

Above fact explains, starting from same benchmark scenario, lower increase of GDP, sectoral output, trade expansion and sectoral composite commodity price reduction under imperfect completion than under perfect competition in response to tariff reduction. In addition to, increased social welfare is lower under monopolistic competition than under perfect competition as equilibrium takes place in case of the former at an output below the socially optimal level.

EXPERIMENT 2 Technological progress in the presence of increasing returns to scale and ‘Consumers preference for variety’.

We simulated the impact of 5 per cent technological progress and compared the results with perfect competition. We find in most of the cases, imperfect competition results map with perfect competition results with little dissimilarities in magnitude. Under monopolistically competitive market structure with increasing returns to scale and consumer’s preference for variety, a 5 per cent technical progress leads to an expansion of GDP, gross investment, household consumption, sectoral export and import and sectoral real output roughly by 5 per cent. As the case of perfect competition, composite commodity

prices in the domestic market lowered down by more than 4.5 per cent and domestic exchange rate is appreciated by 4.86 per cent. The number of firms has been increased in almost all sectors.

Domestic policy towards skill formation and R&D promotion for ensuring technical progress may lead to growth of the economy in the long run. A continuous improvement of technology over time will increase output and gross investment that could expand existing capital stock in the next period. With higher per capita capital stock economy could achieve sustainable development in the long run.

EXPERIMENT 3 Greater foreign capital inflow in the presence of increasing returns to scale and ‘Consumers preference for variety’.

International capital mobility and integration of global financial markets have been emerged as many developed countries removed capital controls after 1970s. Developing country like India too adopted liberalization policies towards greater inflow of foreign capital in order to augment domestic savings. As in the case of perfect competition we simulate a 25 per cent increase of foreign capital under increasing returns to scale and consumers’ preference for variety.

Under monopolistic competition also, foreign capital inflow appreciates exchange rate, increases imports and reduces export without much differences in magnitudes as compared to perfect competition case. Household consumption increases from increased real income as composite commodity prices are lowered down due to the competition among firms and higher capacity utilization. There is a small increase of number of firms in almost every sector.

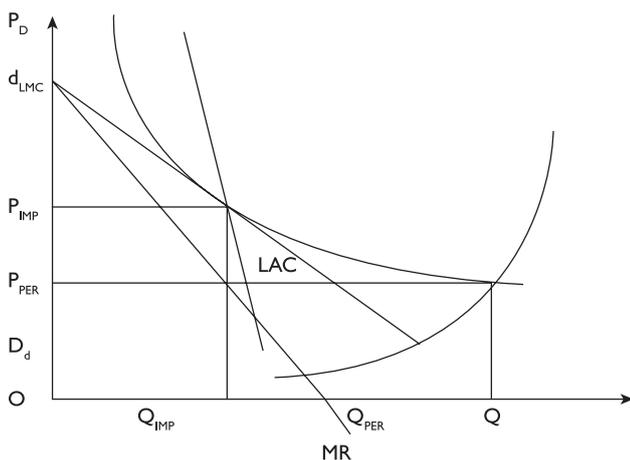

Figure 4. Price and Output under Monopolistic Competition

Concluding Remarks

In this paper we studied trade policy consequences under market imperfection. In the present day globalized scenario emergence of scale economy, diverse consumer preference and market structure oriented industry behaviour give rise to the rethinking of international trade especially in the direction of intra-industry trade. Our study reveals that under imperfect competition, reduction of import tariff follows standard trade theory results, that is, export and import expand, exchange rate deteriorates, domestic sectoral output increases and composite commodity price falls. However, variety driven trade could not produce any greater domestic output, trade expansion

(higher volume of export and import) and gains from trade as compared to standard perfect competition case. This is probably because, increased gains from trade owing to the presence of third source of comparative cost advantage, namely, ‘Variety driven trade’ or gains from specialization is completely offset by excess capacity loss naturally present in imperfectly competitive market structures. Comprehensively, it could be stated that the presence of increasing returns to scale and imperfect competition although puts some insights into the basis of international trade; it could not alter standard trade theory results based on perfect competition. This striking result for the Indian economy might be due to fact that, intra-industry trade and consumers’ preference for variety, particularly horizontal product differentiation is not truly visible in large agricultural sector and informal manufacturing sectors where globalization and foreign investment have not been promoted much.

However, the practical relevance of introducing market imperfection, increasing returns and monopolistic competition, into the framework of trade and globalization seems to be noteworthy. Despite less emergence of variety driven trade in agrarian sectors of the Indian economy, it is very prominently visible in globalized service sectors and capital goods industries. People can freely opt for their chosen varieties from large number of alternatives in mobile computing sector, laptop and television or in the market of service sectors like, Insurance, Banking, Education and Healthcare services. Certainly this would provide extra welfare gain to the consumers. From the policy makers perspectives it is thus worthwhile to allow higher FDI in the sectors like insurance, pension funds, education and other service sectors. Risk and vulnerability associated with higher exposure to the global capital market can be surpassed by the higher welfare gain achieved by the consumers belonging in a world of wide range of varieties and opportunities.

Appendix I. Mathematical Structure of the Benchmark CGE Model

Production Block:

$$Y_j = b_j \cdot \left[\prod_h F_{h,j}^{\beta_{h,j}} \right] \tag{1}$$

$$X_{i,j} = ax_{i,j} \cdot Z_j \tag{2}$$

$$Y_j = ay_j \cdot Z_j \tag{3}$$

$$F_{h,j} = \beta_{h,j} \cdot py_j \cdot Y_j / pf_h \tag{4}$$

$$pz_j = ay_j \cdot py_j + \sum_i ax_{i,j} \cdot pq_i + \frac{FC_j}{Z_j} \tag{5}$$

Government behaviour:

$$GINC = Td + Tdc + TInd + NCAT + ENT + TARR - Ts \tag{6}$$

$$Td = \sum_b \tau aud_b \cdot \left[\sum_h pf_h \cdot FF_h \cdot r_{h,b} + GT_b + NCUT_b \right] \tag{7}$$

$$Tdc = tcorp \cdot (OPR + IND) \tag{8}$$

$$OPR = sop \cdot \left[\sum_h pf_h \cdot FF_h + NF_1 + NF_2 \right] \tag{9}$$

$$TInd = \sum_b \tau auz_j \cdot pz_j \cdot Z_j \tag{10}$$

$$TARR = \sum_i \tau aum_i \cdot pm_i \cdot M_i \tag{11}$$

$$Ts = \tau aus \cdot \sum_i pe_i \cdot E_i \tag{12}$$

$$Xg_i = mu \times GDP / pq_i \tag{13}$$

$$GT_b = gt_b \cdot GINC \tag{14}$$

$$GEXP = \sum_i Xg_i + \sum_b GT_b + Ts \tag{15}$$

$$S_G = GINC - GEXP \tag{16}$$

Investment behaviors:

$$Xv_i = lamda_i \cdot \left[Dep + \sum_b Sp_b + Sg + Sc + Sf \cdot \epsilon \right] / pq_i \tag{17}$$

Savings:

$$HHIN_b = \sum_h \left[\sum_h FF_h \cdot pf_h + NF_1 + NF_2 \right] \cdot r_{hb} + NCUT_b + GT_b \tag{18}$$

$$HHIN_b = \left[\sum_h FF_h \cdot pf_h + NF_1 + NF_2 \right] \cdot r_b + NCUT_b + GT_b \tag{18.a}$$

Where $r_b = \sum_h r_{h,b}$

(Appendix I continued)

(Appendix 1 continued)

$$Sp_b = ssp_b \cdot HHIN_b \tag{19}$$

$$Sc = ssc \cdot (OPR + IND) \tag{20}$$

Household consumption:

$$Xp_{i,b} = \alpha_{i,b} \cdot [HHIN_b - Td_b - Sp_b] / pq_i \tag{21}$$

International trade:

$$pm_i = \epsilon \cdot pWm_i \cdot (1 + \tau_{m_i}) \tag{22}$$

$$pe_i = \epsilon \cdot pWe_i \cdot (1 + \tau_{e_i}) \tag{23}$$

$$\sum_i pWe_i \cdot E_i + Sf + \sum_b NCUT_b + NF_1 + NF_2 + NCAT + Ts = \sum_i pWm_i \cdot M_i \tag{24}$$

Armington function:

$$Q_i = \gamma_i [\delta_{m_i} \cdot M_i^{\epsilon_{m_i}} + \delta_{d_i} \cdot D_i^{\epsilon_{d_i}}]^{\frac{1}{\epsilon_i}} \tag{25}$$

$$\frac{M_i}{Q_i} = \left[\gamma_i^{\epsilon_{m_i}} \cdot \delta_{m_i} \cdot \frac{pq_i}{pm_i} \right]^{\frac{1}{1-\epsilon_{m_i}}} \tag{26}$$

$$\frac{D_i}{Q_i} = \left[\gamma_i^{\epsilon_{d_i}} \cdot \delta_{d_i} \cdot \frac{pq_i}{pd_i} \right]^{\frac{1}{1-\epsilon_{d_i}}} \tag{27}$$

Transformation function:

$$Z_i = \theta_i \cdot [x_{ie_i} \cdot E_i^{p_{hi}} + x_{id_i} \cdot D_i^{p_{hi}}]^{\frac{1}{p_{hi}}} \tag{28}$$

$$\frac{E_i}{Z_i} = \left[\theta_i^{p_{hi}} \cdot x_{ie_i} \cdot (1 + \tau_{ind}) \cdot \frac{pz_i}{pe_i} \right]^{\frac{1}{1-p_{hi}}} \tag{29}$$

$$\frac{D_i}{Z_i} = \left[\theta_i^{p_{hi}} \cdot x_{id_i} \cdot (1 + \tau_{ind}) \cdot \frac{pz_i}{pd_i} \right]^{\frac{1}{1-p_{hi}}} \tag{30}$$

Market clearing condition:

$$Q_i = \sum_b Xp_{i,b} + Xg_i + Xv_i + \sum_j X_{i,j} \tag{31}$$

$$FF_h = \sum_j F_{h,j} \tag{32}$$

Fictitious Objective function:

$$UU = \sum_b \prod_i Xp_{i,b}^{\alpha_{i,b}} \tag{33}$$

Appendix IA. List of Endogenous Variables

- Y_j = Combined input used in j th activity.
- $F_{h,j}$ = Demand for basic input h in j th activity.
- Z_j = Output of j th activity.
- py_j = Price of combined input in j th activity.
- pf_h = Price of basic input h .
- pq_i = Price of the i th commodity.
- $GINC$ = Total government income.
- Td = Household income tax.
- Tdc = Corporate tax.
- $TInd$ = Indirect tax.
- pf_h = Factor price of the h th factor.
- FF_h = Factor demand of the h th factor.
- GT_b = Government transfer to the b th household.
- gt_b = Government income share transferred to b th household.
- $Xp_{i,b}$ = b th household consumption of the i th good.
- Xg_i = Government consumption of the i th good.
- $X_{i,j}$ = i th sector's output goes to j th sector as intermediate input.
- Xv_i = i th commodity used as investment good.
- pq_i = Price of the i th commodity.
- pe_i = Price of export.
- Sg = Government savings.
- Sp_b = Private savings of the b th household.
- Sg = Government savings.
- Sc = Corporate savings.
- ϵ = Exchange rate.
- $HHIN_b$ = Income of the b th household.
- pe_i = Export price of good i in domestic currency.
- pm_i = Imports price of good i in domestic currency.
- pd_i = Price of domestic good.
- pz_i = Supply price of the i th good.
- pWe_i = World export price.
- pWm_i = World import price.
- E_i = Export of good i .
- M_i = Import of good i .
- ϵ = Exchange rate.
- Q_i = Output composite good.
- D_i = Output domestic good.
- UU = Social welfare function.

Appendix IB. List of Exogenous Variables

- b_j = Production function shift parameter.
- $\beta^{j,h}$ = Share of h th input within combined input in j th activity.
- $ax_{i,j}$ = Per unit requirement of i th commodity in j th activity as intermediate input.

ay_j	= Per unit requirement of combined input in j th activity.	phi_i	= Constant determining elasticity of substitution in transformation function.
$r_{h,b}$	= h th factor income share of b th household.	$tind$	= Indirect tax rate.
ENT	= Income of the government from entrepreneurial activity.	$taum_i$	= Import tariff rate.
$taud_b$	= Share of total household income paid as income tax by b th household.	$taus$	= Export subsidy rate.
mu_i	= Share of government expenditure on i th commodity.	$NCUT_b$	= Net current transfer to b th household.
$NCAT$	= Net transfer to government.	$tcorp$	= Share of corporate income to tax.
Sf	= Foreign savings at world prices.	OPR	= Operating profit.
$lamda_i$	= Proportion of savings converted into investment.	IND	= Interest on debt.
Dep	= Depreciation of capital.	sop	= Share of operating profit to total factor income.
FF_h	= Total factor demand of the h th factor.	NF_1	= Net labour income earned abroad.
$gamma_i$	= Scale parameter in Armington function.	NF_2	= Net capital income earned abroad.
$deltad_i$	= Share coefficient of domestic good in Armington function.	$Tpurhh$	= b th household purchase tax.
$deltam_i$	= Share coefficient of import good in Armington function.	$Tpurg$	= Government purchase tax.
eta_i	= Constant determining elasticity of substitution in Armington function.	$Ting$	= Taxes on intermediate.
$theta_i$	= Scale parameter transformation function.	$Tinv$	= Taxes on investment good.
xie_i	= Share parameter of export in transformation function.	Ts	= Taxes on export.
xid_i	= Share parameter of domestic good in transformation function.	$tpurhh_b$	= Share of household purchase paid as purchase tax by b th household.
		$tpurg$	= Share of government purchase paid as purchase tax.
		$ting$	= Share of intermediate good purchase to tax.
		$tinv$	= Share of investment to tax.
		$taus$	= Share of export paid as tax.
		FC_j	= Fixed cost in the j th sector.

Appendix 2. Alternative Closure Rules

Table 4. Alternative Closure Rules

Government	Rest of the World	Saving-Investment
Gov-1 Flexible government savings, fixed Direct tax rates.	ROW-1 Fixed foreign saving, Flexible exchange rate.	S-1 Fixed capital formation, Uniform MPS point change for selected institution.
Gov-2 Fixed government savings Uniform direct tax rates	ROW-2 Flexible foreign saving, fixed real exchange rate.	S-2 Fixed capital formation, scaled MPS for selected institution.
Gov-3 Fixed government savings Scaled direct tax for selected institution.		S-3 Flexible capital formation, Fixed MPS for all non-governmental institutions.
		S-4 Fixed investment and government consumption absorption shares (flexible quantities) Uniform MPS, point change for selected institution.
		S-5 Fixed investment and government consumption absorption shares. (flexible quantities) Scaled MPS for selected institution.

Appendix 3. Calibrated Values of the Parameters**Table 5.** Calibrated Values of the Parameters

Parameter	Description	Primary	Secondary	Infra.	Service
β_i (Labour)	Share parameter in production function.	0.561	0.577	0.449	0.582
β_i (Capital)	Share parameter in production function.	0.439	0.423	0.551	0.418
b_j	Production function shift parameter.	1.98	1.97	1.98	1.97
ay_i	Composite factor requirement.	0.766	0.283	0.621	0.786
mu_i	Government consumption share.	0.01	0.207	0.075	0.996
$taum_i$	Import tariff rate.	0.4	0.14	0.14	0.14
$tind_i$	Indirect tax rate.	-0.004	0.012	0.010	0.003
$gamma_i$	Scale parameter in Armington function.	1.624	1.655	1.077	1.98
$deltam_i$	Share parameter of imported good.	0.29	0.285	0.171	0.186
$deltad_i$	Share parameter of domestic good.	0.710	0.715	0.829	0.814
eta_i	Elasticity of substitution in Armington.	0.5	0.5	0.5	0.5
$theta_i$	Scale parameter in transformation func.	54980	138610	78534	63972
xie_i	Share parameter of export.	4.020E-7	5.41E-8	1.29E-7	2.5E-7
xid_i	Share parameter of domestic good (Trans).	7.9559E-8	2.034E-8	4.77E-8	6.33E-8
phi_i	Substitution elasticity in transformation.	1.5	1.5	1.5	1.5
Parameter	Description	RHH1	RHH2	UHH1	UHH2
$taud_b$	Direct tax rate.	0.018	0.41	0.017	0.190
gt_b	Parameter for govt. transfer.	0.189	0.413	0.365	0.048
ssp_b	Propensity to save for households.	0.14	0.344	0.243	0.029
r_b (Labour)	Labour income share for households.	0.246	0.223	0.128	0.041
r_b (Capital)	Capital income share for households.	0.117	0.268	0.563	0.078

Notes

- For an example, estimated long-run gains from Canadian trade liberalization ranges 8–12 per cent larger than gains suggested by conventional method (Cox & Harris, 1983, 1984).
- In Indian context I/O table is published by Central Statistical Office (CSO) in every five years gap. Saluja and Yadav (2006) constructed SAM for India using I/O matrix for the year 1999.
- Net indirect tax mentioned in the SAM has been classified into domestic indirect tax and import tariff.
- In the Indian context government savings in most of the cases is negative that constitute large part of country's fiscal deficit. Expenditure of the government is usually determined in annual budget.
- Market structure and foreign trade.
- See Brander and Spencer (1985) and Brander and Krugman (1983) in this connection.
- Purchase cost of them is called 'sunk' cost as the benefit from them may be accrued in the subsequent years. Gross domestic capital formation provides an addition to the stock of fixed capital like building, machinery, equipments etc.
- This implies total industry fixed cost is constant and does not depend on entry or exit of new firms.
- Here $p_z(j)$ is the price of j th product, $a_y(j)$ unit requirement of composite input for the j th product, $a_x(i,j)$ is the unit requirement of the i th input for the production of j th output. $FC(j)$ is the total fixed cost and $Z(j)$ is total domestic production of j th output.

10. Considering each variety is equally priced.
11. We took same number of firms in each sector as 10. On an average competition among sellers lie within 10 varieties while consumer's preferences are usually confined within, on an average, 10 varieties of the same product.
12. We get few empirical support of our price elasticity computed value. In case of electricity in services obtained value is -0.3 , in case of bus transport calculated value lies between -0.232 and -0.523 . For the tobacco product price elasticity lies between -0.4 and -0.9 .
13. Since the SAM of 2003–2004 is a balanced SAM and our intention is to empirically examine the directional movement of different macroeconomic variables in response to trade policy change, results will not be much affected only because of calibrating model parameters using 2003–2004 SAM instead of using some recent SAM.
14. This value can directly be obtained from SAM.
15. For the necessary underlying assumptions, consider immediately preceding section.
16. For more elaborate discussion, see the preceding section. Price elasticities are considered for (i) Primary sector, (ii) Secondary sector, (iii) Infrastructure and (iv) Other service sector as -0.35215 , -0.2642 , -0.289 , -0.3107 , respectively. We obtained these values from various economic literatures on Indian economy.
17. In the presence of fixed cost, equilibrium does not take place at the minimum point of LAC.
18. Welfare function is taken in log linear form. In case of perfect competition base run welfare is $5.10E+07$.E stands for shifting decimal place in the right side.
